ABSTRACT

In this paper we consider a mixed formulation for study of the bilaplacian problem with obstacle constraints in conjunction with the penalization method. The idea is based on the decomposition of the bilaplacian operator into two coupled laplacians and of course by choosing suitable spaces. The numerical advantage is to allow the solution of coupled systems with nice matrices having the M-matrix property. Moreover, the computed solution of the problem requires less execution time with respect to the discrete system of the bilaplacian problem. For simulation, we test the efficiency of a variety of iterative relaxation methods and discuss their numerical performances.

Keywords: Mixed formulation, Unilateral constraint, Bilaplacian problem, Method of penalization.
1. Introduction

The obstacle problems are a very important class of nonlinear problems which have been widely studied mainly for 2nd order operators from both theoretical and numerical point of views by Duvaut and Lions (1972), Glowinski et al. (1981), Hlavacek et al. (1988), Leger and Pozzolini (2009), Lions (1969, 1976). Early research had been concerned with the study of the 2nd order problems with constraints. We refer, particularly, to the book of Duvaut and Lions (1972) and Glowinski et al. (1981).

In Lions (1969), the author stated and established a general result of existence and uniqueness of solution for the stationary and the evolutive problems. These problems are, generally, encountered in various domains such as mechanics, physics, economics, optimal control, etc., and correspond to strongly nonlinear problems. The nonlinearity is due to the nonlinear nature of the constraints imposed on the solution inside the domain \( \Omega \) or on the boundary \( \partial \Omega \).

In Duvaut and Lions (1972), we can find a unified approach for both the classical obstacle and Signorini problems. The main difference between the two distinct problems resides in the choice of a particular functional defined by an integral either on the boundary for the Signorini problem or in the domain for the obstacle problem. We are now ready to state the model problem:

Find \( u \in V \) such that

\[
(P) \quad \begin{cases}
Au = f & \text{in } \Omega, \\
u \geq q & \text{in } \Omega, \\
(Au - f)(u - q) = 0 & \text{in } \Omega,
\end{cases}
\]

\( (a) \quad (b) \quad (c) \quad (d) \)

where \( A \) is, generally, an elliptic or parabolic operator; \( f \) is a given function belonging to some space which ensures the regularity of the solution \( u \); \( q \) represents the unilateral constraint and \( V \) is a Hilbert space. The equation \( (c) \) is called the complementarity condition.

The second order problem is still a subject of several studies, we cite, for example, a recent work (see Chau et al. (2017)), where the authors have studied a 3D problem with unilateral constraints on the boundary arising in fluid mechanics and proposed an implicit scheme for the discretization of the time dependent part of the operator. Hence, the problem is reduced to the solution of a sequence of stationary problems by the domain decomposition method using an asynchronous parallel iterative algorithm.
A Mixed Formulation in Conjunction with the Penalization Method for Solving the Bilaplacian Problem with Obstacle Type Constraints

Fourth order problems have received much less attention but however in the last two decades they regained a renewed interest because of their important applications (see Amara and El Dabaghi (1996), Caffarelli Luis and Friedman (1979), Glowinski and Pironneau (1984), Haslinger (1978), Lin et al. (2012), Qingping and Shen (1994) and Brenner (2017)). Accordingly, a great importance has been given to the construction of iterative numerical algorithms which take efficiently into account the constraint (see Ciarlet and Glowinski (1984), Ciarlet and Lions (1996) and Westbrook (1990)).

Note that these problems are considered as ill-posed problems (see Muvasharkhan and al. (2014). However the theorem of maximum principle cannot be applied to them contrary to 2nd order problems. We cite some relevant references; in Muvasharkhan and al. (2014), the authors have reduced the ill-posed problem to an optimal control problem and established necessary conditions of optimality. In Fernane and Ayadi (2011), the obtained results show that the discretization of the obstacle problem for a thin elastic plate by the mixed finite element method of a variational formulation can be obtained directly from the hypersphere inequality and led to two optimal convergence rates. For our part, we are interested in the study of the bilaplacian problem subject to unilateral constraints using a technique of mixed formulation due to Ciarlet and Raviart (1974). We can find some properties of induced functional spaces concerning this technique (see Bernardi et al. (1992)).

The numerical advantage is that it requires only the use of $C^0$ finite elements, contrary to the initial formulation using the bilaplacian which requires $C^1$--continuity. The idea is based on the decomposition of the bilaplacian operator into two coupled laplacians and of course by choosing suitable spaces. For this purpose, let $u$ be a solution of the bilaplacian problem and introduce the function $\phi$, defined by $\Delta u = -\phi$, where $\phi \in L^2(\Omega)$ and $\Delta \phi \in H^{-1}(\Omega)$ (which is useful because $\Delta u$ represents the bending moments in elasticity and the vorticity in hydrodynamics).

Several authors have studied this decomposition technique more specially for the bilaplacian equation without obstacle (see Amara and El Dabaghi (1996), Bishnu and Lamichhane (2011) and Scholz (1978)). For example, Kezan van and Vanninathan (1977) have studied the mixed finite element method which gives not only the approximation $u_h$ of $u$ but also the approximation $\phi_h$ of $\Delta u$, where $\phi_h$ and $u_h$ are the approximations of $\phi$ and $u$ respectively. In Ciarlet and Glowinski (1984), the authors have introduced the polynomials of degree $k$, with $k \geq 2$ for the particular case of a polygonal domain and obtained the following convergence order.
Hannache, A., Laouar, A. and Sissaoui, H.

\[ \| \phi - \phi_h \|_{0,\Omega} + |u - u_h|_{1,\Omega} = O(h^{k-1}), \]

where \( \| . \|_{0,\Omega} \) and \( | . |_{1,\Omega} \) are classical norms.\(^1\)

Amara and El Dabaghi (1996) proposed a method which preserves the property of the bilaplacian equation (without obstacle) by formulating it as an operator on opposite boundaries. This method allows the use of conjugate gradient technique which requires a solution of two Laplace-Dirichlet problems by iteration (see Glowinski and Pironneau (1984)). The obtained results confirm the efficiency of the method, especially regarding the computation of \( \phi \) in the vicinity of the boundary domain.

In this study, we look for vertical displacements \( u \) along the \( oz \) axis of a square elastic plate \( \Omega \) perfectly clamped on its edges (or with simply supported boundary conditions), subject to a force \( f \) perpendicular to the thin elastic plate and displaced by a rigid obstacle. For this, we propose weak variational formulations and state the advantages and shortcomings of each of them as well as their approximations by an appropriate finite element method. On the one hand, the mixed formulation is more suitable than that of the above problem \((P)\) since it reduces the 4\textsuperscript{th} order problem to two 2\textsuperscript{nd} order and hence requiring less regularity of the solution.

On the other hand, it has a numerical advantage since it allows to solve coupled systems with nice matrices having the M-matrix property. Moreover, the computed solution of the problem requires less execution time with respect to the discrete system of the bilaplacian problem. So, the goal of this paper is to combine the mixed formulation with the penalization method. The latter permits the removal of the constraints by incorporating them into the functional. Afterwards, we complete this study by numerical simulations, testing the efficiency of the iterative relaxation methods.

The outline of the paper is as follows. Section 2 describes the problem, the variational formulations and the existence and uniqueness of the solution to the problem. Section 3 introduces the decomposition technique and gives the existence and uniqueness of the solution to the coupled sub-problems. Section 4 applies the penalization method to the coupled sub-problems. Section 5 studies the discrete analogues and the last section displays the numerical results.

\(^1\forall v \in L^2(\Omega), \|v\|_{0,\Omega} = \left( \int_{\Omega} |v|^2 \, d\Omega \right)^{1/2} \) and \( \forall v \in H^1(\Omega), |v|_{1,\Omega} = \left( \int_{\Omega} |\nabla v|^2 \, d\Omega \right)^{1/2} \).
A Mixed Formulation in Conjunction with the Penalization Method for Solving the Bilaplacian Problem with Obstacle Type Constraints

2. Description of the problem

In elasticity, the problem describes, in $2D$ space, the vertical displacements $u$ along the $oz$ axis of a thin elastic plate $\Omega$ perfectly clamped on its edges (or with simply supported boundary condition), subject to a force $f$ perpendicular to this plate and in contact with a rigid obstacle $q$ (see Figure 1).

Let $\Omega$ be a bounded open set of $\mathbb{R}^n$ with boundary $\partial\Omega$ sufficiently regular and $V$ a Hilbert space. We seek a function $u \in V$ such that

$$\Delta^2 u = f \quad \text{in } \Omega,$$

$$u \geq q \quad \text{in } \Omega,$$

$$(\Delta^2 u - f)(u - q) = 0 \quad \text{in } \Omega,$$

with clamped boundary conditions

$$u = \frac{\partial u}{\partial n} = 0 \quad \text{on } \partial\Omega,$$

or with simply supported boundary conditions

$$u = \Delta u = 0 \quad \text{on } \partial\Omega,$$

where the bilaplacian operator $\Delta^2$ is defined by

$$\Delta^2 = \Delta(\Delta) = \frac{\partial^4}{\partial x^4} + 2\frac{\partial^4}{\partial x^2 \partial y^2} + \frac{\partial^4}{\partial y^4},$$

the given function $f$ belongs to $L^2(\Omega) \cap H^4(\Omega)$ and $n$ is an external normal vector to $\Omega$; here $V = H^4_0(\Omega)^2$

Note that the equation (3) represents the complementarity condition and the problem (1)-(4) is considered as a free boundary problem which can be interpreted as follows.

\[
2H^4_0(\Omega) = \left\{ v : \Omega \subset \mathbb{R}^n \to \mathbb{R}, \frac{\partial^k v}{\partial x_{i_1} \ldots \partial x_{i_k}} \in L^2(\Omega), \forall k = 0, 4 \right\} \cap \left\{ v/v = \frac{\partial v}{\partial n} = 0 \text{ on } \partial\Omega \right\}
\]
Hannache, A., Laouar, A. and Sissaoui, H.

The solution $u$ divides the domain $\Omega$ into two subdomains $\Omega_1$ and $\Omega_2$ (see the Figure 1) as shown below

$$\Omega = \Omega_1 \cup \Omega_2,$$

where

$$\Omega_1 = \{ x \in \Omega / u = q \}, \quad \Omega_2 = \{ x \in \Omega / u > q \} \quad \text{and} \quad S = \partial \Omega_1 \cap \partial \Omega_2$$

with $S$ is a priori an unknown interface separating $\Omega_1$ and $\Omega_2$.

![Figure 1: The clamped thin elastic obstacle problem](image)

In the sequel of the analytical study, we will use mainly the boundary conditions (4). Note that a study of the problem (1)-(3) with the boundary conditions (5) can be found in [Bishnu and Lamichhane, 2011]. Knowing that the problem (1)-(4) can be written as an optimization problem. For this, let us consider the following problem

$$J(u) = \inf_{v \in K} J(v),$$

where

$$J(v) = \frac{1}{2} \int_{\Omega} |\Delta v|^2 d\Omega - \int_{\Omega} fvd\Omega,$$

with

$$K = \left\{ v \in H_0^2(\Omega) / v \geq q \right\}^3$$

$$3 \text{H}_0^2(\Omega) = \left\{ v : \Omega \subset \mathbb{R}^n \rightarrow \mathbb{R}, \frac{\partial^k v}{\partial x_{i_1}...\partial x_{i_k}} \in L^2(\Omega), \forall k \in \{0,2\} \cap \left\{ v/v = \frac{\partial v}{\partial n} = 0 \text{ on } \partial \Omega \right\} \right\}$$

A Mixed Formulation in Conjunction with the Penalization Method for Solving the Bilaplacian Problem with Obstacle Type Constraints

Setting

\[ a(u, v) = \int_{\Omega} \Delta u \Delta v d\Omega, \quad (9) \]

where the bilinear form \( a(\cdot, \cdot) \) is none other than the scalar product whose \( H^2(\Omega) \) norm comes from (9).

We know that the Sobolev spaces \( H^2(\Omega) \) and \( H^2_0(\Omega) \) (the space \( H^2_0(\Omega) \) is a closed subspace of the space \( H^2(\Omega) \)) are Hilbert spaces for the norm \( \| \cdot \|_{2,\Omega} \) (see Brezis (1987)).

Let us also set

\[ F(v) = (f, v) = \int_{\Omega} f v d\Omega, \]

where \((\cdot, \cdot)\) denotes the inner product defined in \( L^2(\Omega) \).

Thus the functional \( J \) can be written as follows

\[ J(u) = \frac{1}{2} a(u, u) - F(u). \]

So, the problem (1)-(4) is equivalent to

\[
\begin{cases}
\text{Find } u \in K \text{ such that } \\
J(u) \leq J(v), \forall v \in K.
\end{cases}
\]

(10)

If the minimization problem (10) has one solution satisfying the equations (1)-(4), then the Euler inequality applied to the problem (10) leads to the classical equivalent variational formulation of the boundary value problem

\[
\begin{cases}
\text{Find the solution } u \in K \text{ such that } \\
a(u, v - u) \geq F(v - u), \forall v \in K.
\end{cases}
\]

(11)

Let \( V \) be a reflexive Banach space; the form \( a(u, v) \) is continuous and linear in \( v \) but nonlinear in \( u \), i.e., \( a(u, v) = (Au, v) \), where the operator \( A : V \to V \).

\[^4\forall v \in H^2_0(\Omega) : \| v \|_{2,\Omega}^2 = \left[ \| v \|_{0,\Omega}^2 + \sum_{i=1}^{2} \left\| \frac{\partial v}{\partial x_i} \right\|_{0,\Omega}^2 + \sum_{i,j=1}^{2} \left\| \frac{\partial^2 v}{\partial x_i \partial x_j} \right\|_{0,\Omega}^2 \right]^\frac{1}{2} \]
Thus, the problem (11) can be written as follows

\[
\begin{align*}
\text{Find the solution } u & \in K \text{ such that } \\
(Au, v - u) & \geq F(v - u) \quad \forall v \in K.
\end{align*}
\]  

(12)

The existence and uniqueness of the solution of problem (11) is ensured since the bilinear form \( a(u, v) = \int_{\Omega} \Delta u \Delta v d\Omega \) is continuous and \( V \)-elliptic (here \( V = H^2(\Omega) \)) and the linear form \( F(v) = \int_{\Omega} f.v d\Omega \) is also continuous. Then, according to Lions-Stampacchia theorem, the variational inequality (11) admits a unique solution \( u \in H^0_0(\Omega) \).

The existence and uniqueness of the solution for the problem (12) is also ensured if \( A \) is coercive, i.e.,

\[
\lim_{\|v\| \to \infty} \frac{(Av, v)}{\|v\|} = \infty,
\]

and strictly monotone, i.e.,

\[
(Au - Av, v - u) > 0 \quad \text{for any } u, v \in V.
\]

3. A Mixed formulation for the problem (1)-(4)

Ciarlet and Raviart (1974) proposed a method based on a variational formulation called mixed formulation (decomposition method) in order to use numerically \( P1 \) Lagrange FEM. For our part, we adapt this technique to a problem with unilateral constraints. As said previously, this technique is based on the decomposition of the problem (1)-(4) into two coupled sub-problems. To do this, let \( u \) be a solution of the problem (1)-(4) and introduce now the function \( \phi \) as follows:

\[
\Delta u = -\phi.
\]  

(13)

Substituting (13) into the problem (1)-(4) and introducing the appropriate variational framework, i.e., \( \phi \) in \( L^2(\Omega) \) with \( \Delta \phi \) in \( H^{-1}(\Omega) \) and \( u \) in \( H^1_0(\Omega) \), this new framework will enable us to define an approximate method of class \( C^0 \).
If $u$ is a solution of problem (1)-(4) then a pair $(\phi, u) \in H^2(\Omega) \times H^2_0(\Omega)$ is a solution of the following continuous problem:

$$
(P_{mix}) \begin{cases}
-\Delta \phi = f & \text{in } \Omega, \\
-\Delta u = \phi & \text{in } \Omega, \\
u \geq q & \text{in } \Omega, \\
(\Delta \phi + f)(\Delta u + \phi)(u - q) = 0 & \text{in } \Omega, \\
u = \frac{\partial u}{\partial n} = 0 & \text{on } \partial \Omega.
\end{cases}
$$

To give a variational inequality corresponding to the continuous problem $(P_{mix})$, let $(\Psi, v)$ be a pair of test functions belonging to $H^1_0(\Omega) \times H^1(\Omega)$, where the function $\Psi$ will be test functions associated to $\phi$, and $v$ to the second variable $u$. Note that the values of $u$ do not intervene in the formulation (14) given below, in order to preserve their memory in the continuous problem $(P_{mix})$. Thus, we can introduce the properties that are suitable in the functional space, for which the function $\Psi$ will be generic. The boundary conditions on $\partial \Omega$ are replaced respectively in the systems of equations and in the inequality of the problem $(P_{mix})$ by choosing as functional space $H^1(\Omega) \times H^1_0(\Omega)$ for the unknowns $(\phi, u)$ and $H^1_0(\Omega) \times H^1(\Omega)$ for the pair of test functions $(\Psi, v)$.

Thus, the coupled variational inequalities corresponding to problem $(P_{mix})$ can be written as follows:

$$
\begin{cases}
\text{Find the couple } (\phi, u) \in H^1(\Omega) \times K_1 \text{ such that } \\
 a_1(\phi, \Psi) = L_f(\Psi), \quad \forall \Psi \in H^1_0(\Omega) \quad (i) \\
 a_2(u, v - u) \geq L_\phi(v - u), \quad \forall v \in K_1 \quad (ii)
\end{cases}
$$

where

$$
a_1(\phi, \Psi) = \int_\Omega \nabla \phi . \nabla \Psi d\Omega, \quad L_f(\Psi) = \int_\Omega f . \Psi d\Omega, \\
a_2(u, v) = \int_\Omega \nabla u . \nabla v d\Omega, \quad L_\phi(v) = \int_\Omega \phi . v d\Omega,
$$

and

$$
K_1 = \{ v \in V_1 : v > q \}, \text{ with } V_1 = H^1_0(\Omega) \cap \left\{ v / \frac{\partial v}{\partial n} = 0 \text{ on } \partial \Omega \right\}.
$$

For the existence and uniqueness of solution for the coupled variational inequalities (14), we state respectively the following theorems.
Theorem 3.1. Let \( V (V = H^1(\Omega)) \) be a Hilbert space, the bilinear form \( a_1(\cdot,\cdot) \) is continuous and \( V \)-elliptic and \( L_f(\cdot) \) continuous in \( H^1(\Omega) \). Then, according to Lax-Milgram theorem, the variational equation (14, i) admits a unique solution \( \phi \) belonging to \( H^1(\Omega) \).

In the same way, we state the following theorem for the variational inequality (14, ii).

Theorem 3.2. (Arnăutu and Neittaanmäki (2003)) Let \( V_1 \) be a Hilbert space and \( K_1 \) a nonempty convex and closed subset of \( V_1 \), the bilinear form \( a_2(\cdot,\cdot) \) is continuous and \( V \)-elliptic and let \( L_\phi(\cdot) \) be continuous in \( V_1 \). Then, according to Lions-Stampacchia theorem, the problem (14, ii) admits a unique solution \( u \) belonging to \( V_1 \).

4. Penalization method

In this section, we introduce the penalization method (for more details, see Arnăutu and Neittaanmäki (2003), and Ghennam (2005)) for the problems (11), (12) and (14). To do this, we recall the following definitions.

Definition 4.1. The functional \( f : V \rightarrow \overline{\mathbb{R}} \) is proper if \( f(x) > -\infty \) for all \( x \in V \) and \( f \) does not identically equal to infinity.

Definition 4.2. The functional \( f : V \rightarrow \mathbb{R} \) is lower semi-continuous (l.s.c.) at \( x \), if for every sequence \( \{x^j\}_{j \geq 0} \) converging to \( x \), we have \( f(x) \leq \liminf_{j \to \infty} f(x^j) \).

Let us introduce the functional

\[ \gamma : V \rightarrow \mathbb{R} \cup \{\infty\}, \]

which verifies the following hypotheses

\[ (H1) \quad \gamma \text{ is convex, proper and l.s.c.,} \]

\[ \gamma(v) \geq 0, \forall v \in V \text{ (here } V = H^2_0(\Omega)), \]

\[ \gamma(v) = 0 \text{ if and only if } v \in K. \]

For every \( \varepsilon > 0 \), the penalization of the problem (14) is

\[ \begin{align*}
\text{Find } u_\varepsilon & \in H^2_0(\Omega) \text{ such that} \\
& a(u_\varepsilon, v - u_\varepsilon) + \frac{1}{\varepsilon} \gamma(v) - \frac{1}{\varepsilon} \gamma(u_\varepsilon) \geq F(v - u_\varepsilon), \text{ for any } v \in H^2_0(\Omega). 
\end{align*} \]
A Mixed Formulation in Conjunction with the Penalization Method for Solving the Bilaplacian Problem with Obstacle Type Constraints

**Theorem 4.1.** ([Arnăutu and Neittaanmäki (2003)]) Under the hypotheses \((H_1)\), the problem (15) admits a unique solution for any fixed \(\varepsilon > 0\).

**Theorem 4.2.** ([Arnăutu and Neittaanmäki (2003)]) Let \(u\) be solution of the problem (11) and \(u_{\varepsilon}\) be solution of the problem (15), then

\[
\lim_{\varepsilon \to 0} \|u_{\varepsilon} - u\| = 0,
\]

\[
\lim_{\varepsilon \to 0} \frac{1}{\varepsilon} \gamma(u_{\varepsilon}) = 0.
\]

To penalize the problem (12), let us also introduce the operator \(\beta : V \to V'\) (dual space of \(V\)) which has the following properties:
- \(\beta\) is Lipschitz continuous (globally or locally);
- \(\ker(\beta) = K\), i.e., \(\beta(v) = 0\) if and only if \(v \in K\);
- \(\beta\) is monotone.

For any \(\varepsilon > 0\), the penalized problem associated to (12) is written as follows

\[
\begin{array}{ll}
\text{Find } u_{\varepsilon} \in H^2_0(\Omega) \text{ such that } \\
(Au_{\varepsilon}, v) + \frac{1}{\varepsilon}(\beta(u_{\varepsilon}), v) \geq F(v), \text{ for any } v \in H^2_0(\Omega).
\end{array}
\]  

(16)

To penalize the problem (14), in similar way, we replace in the hypotheses \((H1)\) the space \(V\) by \(H^1_0(\Omega)\) and the subset \(K\) by \(K_1\), so that the problem will be given by

\[
\begin{array}{ll}
\text{Find } (\phi, u_{\varepsilon}) \in H^1(\Omega) \times H^1_0(\Omega) \text{ such that } \\
a_1(\phi_{\varepsilon}, \Psi) = L_f(\Psi), \quad \forall \Psi \in H^1(\Omega), \\
a_2(u_{\varepsilon}, v - u_{\varepsilon}) + \frac{1}{\varepsilon} \gamma(v) - \frac{1}{\varepsilon} \gamma(v_{\varepsilon}) = L_{\phi_{\varepsilon}}(v - u_{\varepsilon}), \quad \forall v \in H^1_0(\Omega).
\end{array}
\]  

(17)

According to theorem 6, problem (17) admits a unique solution for every fixed \(\varepsilon > 0\). To show the strong convergence, we apply theorem 7 to problem (17).

**Penalization algorithm**

The penalization algorithm for the problem (16) is given as follows

\begin{itemize}
  
  \text{S0 : choosing } u^0, \varepsilon_1 \\
  \text{S1 : put } k = 1, \\
  \text{S2 : find } u_k \in V \text{ solution of problem (16), by taking } u^{k-1} \text{ as an initial vector,} \\
  \text{S3 : give a stopping criterion, if } u_k \text{ is "satisfactory" stop,} \\
  \text{otherwise put } k := k + 1, \text{ choose } \varepsilon_{k+1} < \varepsilon_k \text{ and return to S2.}
\end{itemize}
5. Discrete analogues of problems (14) and (17)

Let \( \{V_1,h\}_{h>0} \) be a family of closed subspaces of \( V_1 \) (finite dimensional). Let \( \{K_1,h\}_{h>0} \) be also a family of convex, closed and not empty subsets of \( V_1 \) such that \( K_1,h \subset V_1,h \) for every \( h \). The family \( \{K_1,h\}_{h>0} \) approximates the set \( K_1 \), i.e., \( \lim_{h \to 0} K_1,h = K_1 \), if the following conditions are satisfied:

- if \( \{v_h\}_{h>0} \) is a sequence such that \( v_h \in K_1,h \), for every \( h > 0 \) and \( v_h \to v \) weakly in \( V_1 \), then \( v \in K_1 \);
- for any \( v \in K_1 \), there exists a sequence \( \{v_h\}_{h>0} \) such that \( v_h \in K_1,h \) for any \( h > 0 \) and \( v_h \to v \) strongly in \( V_1 \).

Thus, we use the FEM discretization. To this end, we introduce a grid of equidistant nodes as follows: \( x_i = ih \), for \( i = 0, 1, \ldots, N \) with \( h = 1/N \) and \( y_j = jk \), for \( j = 0, 1, \ldots, M \) with \( k = 1/M \) (for simplicity we take \( N = M \)).

The subspace \( V_1,h \subset V_1 \) is defined by

\[
V_1,h = \{ v_h \in H^1(\Omega) \cap C(\Omega) / v/\Gamma \in P_1 \ \text{on each triangle} \}
\]

and

\[
\tilde{V}_{1,h} = \{ v_h \in V_{1,h} \text{ such that } v_h = \frac{\partial v_h}{\partial n} = 0 \ \text{on } \partial \Omega \}.
\]

The discrete convex set:

\[
K_{1,h} = \{ v_h \in \tilde{V}_{1,h} / v_h(x_i,y_j) \geq q(x_i,y_j) \text{ in } \Omega, \text{with } (x_i,y_j) \ \text{the nodal points} \}
\]

The discretization of problems (14) is given by

\[
\begin{cases}
\text{Find the couple } (\phi_h,u_h) \in V_{1,h} \times \tilde{V}_{1,h} \text{ such that } \\
a_1(\phi_h,\Psi_h) = L_f(\Psi_h), \quad \forall \Psi_h \in \tilde{V}_{1,h}(\Omega), \quad (i_h) \\
a_2(u_h,v_h-u_h) \geq L_\phi(v_h-u_h), \forall v_h \in K_{1,h}. \quad (ii_h)
\end{cases}
\]

Now, constructing the discrete analogue of the penalized problem (17), any \( v_h \in V_{1,h} \) is represented by the vector of its coefficients which belong to \( R^{N+1} \).

We denote by respectively \( v_{i,j} \) and \( q_{i,j} \) the \( v_h(x_i,y_j) \) and \( q(x_i,y_j) \), hence, \( K_{1,h} \) may be reduced to \( R_{1,h} \subset R^{N+1} \).

For \( i,j = 0,N-1, \), \( R_{1,h} \) is defined by

\[
R_{1,h} = \left\{ v_{i,j} \in (R^{N+1})/ / v_{i,j} \big|_{\partial \Omega} = \frac{\partial v_{i,j}}{\partial n} \big|_{\partial \Omega} = 0 \text{ and } v_{i,j} \geq q_{i,j} \right\}.
\]
Let us now introduce the function

\[ T : \mathbb{R}^{N+1} \rightarrow \mathbb{R}, \]

\[ T(v) = \frac{1}{2} \sum_{i,j=0}^{n} ((v_{i,j} - q(x_i, y_j))^2 \text{ for } \{ v_{i,j} \}_{i,j=0}^{N}, \]

where \((v_{i,j} - q(x_i, y_j))^2\) is the negative part of \((v_{i,j} - q(x_i, y_j))\) for \(i, j = 0, ..., N\), and defined by

\[ (v_{i,j} - q(x_i, y_j))^2 = \max_{0 \leq i,j \leq N} \{0, (q(x_i, y_j) - v_{i,j})\}. \]

For \(i, j = 0, 1, ... N\), we have

\[ \frac{\partial T}{\partial v_{i,j}}(v) = (v_{i,j} - q(x_i, y_j))^2 \frac{\partial}{\partial v_{i,j}} (v_{i,j} - q(x_i, y_j))^2 = -(v_{i,j} - q(x_i, y_j)). \]

We define the operator \(\eta : \mathbb{R}^{N+1} \rightarrow \mathbb{R}^{N+1}\) as follows:

\[ \eta(v) = \nabla T(v), \forall v \in \mathbb{R}^{N+1}. \quad (20) \]

**Lemma 5.1.** (Arnăutu and Neittaanmäki [2003]) The operator \(\eta : \mathbb{R}^{N+1} \rightarrow \mathbb{R}^{N+1}\) defined by (20) verifies the following properties:

- \(\eta\) is Lipschitz continuous,
- \(\eta(v) = 0\) if and only if \(v \in R_{1,h}\),
- \(\eta\) is monotone.

The discrete analogue of the penalized problems (17) are written as follows

\[
\begin{cases}
\text{Find } (\phi_{\varepsilon,h}, u_{\varepsilon,h}) \in V_{1,h} \times \tilde{V}_{1,h} \text{ such that} \\
A_{1,h} \phi_{\varepsilon,h} = f_h \\
A_{2,h} u_{\varepsilon,h} + \frac{1}{\varepsilon} \eta(u_{\varepsilon,h}) = \phi_{\varepsilon,h}
\end{cases}
\quad (21)
\]

where \(A_{1,h}\) and \(A_{2,h}\) are respectively the discretization matrices of the problems (17 i) and (17 ii).

For simplicity of notation, we drop the indices \(\varepsilon\) and \(h\) everywhere in the sequel and replace the indices \(i, j\) in the terms \(u_{i,j}\) and \(q_{i,j}\) by choosing a single indice. For \(i = 0, N-1\), the systems (21) become
Hannache, A., Laouar, A. and Sissaoui, H.

\[
\begin{align*}
\sum_{l=0}^{N-1} a_{i,l}^{(1)} \phi_l &= f_i, \\
\sum_{l=0}^{N-1} a_{i,l}^{(2)} u_l - \frac{1}{\varepsilon} (u_i - q_i) &= \phi_i,
\end{align*}
\]  
\tag{22}

where \((a_{i,l}^{(1)})_{i,l=0,...,N-1}\) and \((a_{i,l}^{(2)})_{i,l=0,...,N-1}\) are respectively the coefficients of the discretization matrices \(A_{1,h}\) and \(A_{2,h}\).

The linear systems (22, \(i'\)) can be solved, for example, by Gauss-Seidel iterative method and the nonlinear system (22, \(ii'\)) by S.O.R method.

For \(l = 0, ..., N - 1\), there exist two cases:

1. \(u_i \geq q_i\), then \((u_i - q_i) = 0\) for \(i = 0, N - 1\) and the system (22 - \(ii'\)) becomes

\[
\begin{align*}
\sum_{l=0}^{N-1} a_{i,l}^{(1)} \phi_l &= f_i, \\
\sum_{l=0}^{N-1} a_{i,l}^{(2)} u_l &= \phi_i.
\end{align*}
\]  
\tag{23}

We solve the first system (23) by Gauss-Seidel method and the second system by the S.O.R method. At the \(k^{th}\) iteration, for \(i = 0, N - 1\), we have

\[
\begin{align*}
\phi_i^{k+1} &= - \frac{1}{a_{i,i}^{(1)}} \left( f_i + \sum_{l=0}^{i-1} a_{i,l}^{(1)} \phi_l^{k+1} + \sum_{l=i+1}^{N-1} a_{i,l}^{(1)} \phi_l^{k} \right), \\
u_i^{k+1} &= (1 - \omega) u_i^k - \frac{\omega}{a_{i,i}^{(2)}} \left( \phi_i^{k+1} + \sum_{l=0}^{i-1} a_{i,l}^{(2)} u_l^{k+1} + \sum_{l=i+1}^{N-1} a_{i,l}^{(2)} u_l^k \right),
\end{align*}
\]  
\tag{24}

where \(\omega\) is the relaxation parameter.

2. \(u_i < q_i\), then \((u_i - q_i) = q_i - u_i\) for \(i = 0, N - 1\) and the coupled systems (22) become

\[
\begin{align*}
\sum_{l=0}^{N} a_{i,l}^{(1)} \phi_l &= f_i, \\
\sum_{l=0}^{N} a_{i,l}^{(2)} u_l - \frac{1}{\varepsilon} (q_i - u_i) &= \phi_i.
\end{align*}
\]  
\tag{25}

54 Malaysian Journal of Mathematical Sciences
A Mixed Formulation in Conjunction with the Penalization Method for Solving the Bilaplacian Problem with Obstacle Type Constraints

At the $k^{th}$ iteration, for $i = 0, N - 1$, we have

$$ \begin{cases} 
\phi_{k+1}^{i} = -\frac{1}{a_{i,i}} \left( f_{i} + \sum_{l=0}^{i-1} a_{i,i}^{(1)} \phi_{k+1}^{i} + \sum_{l=i+1}^{N-1} a_{i,i}^{(1)} \phi_{k}^{i} \right), \\
u_{k+1}^{i} = (1 - \omega) u_{k}^{i} - \frac{\omega}{a_{i,i}} \left( \tilde{\phi}_{k+1}^{i} + \sum_{l=0}^{i-1} a_{i,i}^{(2)} u_{k+1}^{i} + \sum_{l=i+1}^{N-1} a_{i,i}^{(2)} u_{k}^{i} \right), 
\end{cases} \quad (26)$$

where $\tilde{a}_{i,i} = a_{i,i}^{(2)} + \frac{1}{\varepsilon}$ and $\tilde{\phi}_{i} = \phi_{i} + \frac{1}{\varepsilon} q_{i}$.

6. Numerical examples

To illustrate the above described study, we propose two examples.

**Example 1.** We take $f \equiv 0$ and

$$ q(x, y) = \begin{cases} 
-\frac{2}{5} + \sqrt{\frac{1}{4} - (x - \frac{1}{2})^2 + (y - \frac{1}{2})^2}, \text{ if } (x - \frac{1}{2})^2 + (y - \frac{1}{2})^2 \leq \frac{1}{3}, \\
0, \text{ otherwise.}
\end{cases} $$

Also, we take $\Omega = (0, 1)^2$, where the right hand side $f$ of the equation (1) is computed by using the below exact solution

$$ u(x, y) = (e^x + (x + 1)e^y)x^2y^2(1 - x)^2(1 - y)^2, $$

which satisfies the clamped boundary condition $u = \frac{\partial u}{\partial n} = 0$ on $\partial \Omega$.

Let’s carry out a number of tests to determine the best choice of the relaxation parameter $\omega$ which makes it possible to reduce the iteration number and the execution time of the algorithm (23)-(26).

For this, we use the penalization parameter $\varepsilon = 10^{-4}$ and the various norms $\frac{|u - u_h|_{0,\Omega}}{|u|_{0,\Omega}}$, $\frac{|u - u_h|_{1,\Omega}}{|u|_{1,\Omega}}$ and $\frac{|\phi - \phi_h|_{0,\Omega}}{|\phi|_{0,\Omega}}$.

We display the results, for $h = 1/64$, in Table 1 and in Table 2, respectively.

We remark that the most appropriate parameter is $\omega = 1.8$. We display, in Table 2, the discretization errors along with the rates of convergence in various norms, for example, at the some nodes: for N1 to N9 (see Figure 2).
Table 1: Tests for several values of $\omega$

| N3    | 1.30302e-01          | 1.89139e-01          | 3.34937e-01          |
| N4    | 3.99107e-02          | 8.32646e-02          | 1.88319e-01          |
| N5    | 1.08809e-02          | 3.88438e-02          | 9.92016e-02          |
| N6    | 2.82773e-03          | 1.89646e-02          | 5.08074e-02          |
| N7    | 7.19891e-04          | 9.41839e-03          | 2.56967e-02          |
| N8    | 1.81559e-04          | 4.70081e-03          | 1.29204e-02          |
| N9    | 1.49139e-04          | 3.99039e-03          | 1.01139e-02          |

In the same manner, we can perform similar tests for the parameter of penalization. According to the above results, we can see that the method is convergent and the precision of the solution is acceptable for practical purposes.

Example 2. In this example, we apply the previously described method to problem (1)-(3) with boundary conditions (5), i.e., a square plate simply supported on $\partial\Omega$. We take an example (see Gourdin and Boumahrat (1989)) and we adapt it to our situation. The function $f$ is given by

$$f = \frac{k(x, y)}{D}$$

where $k$ is a supporting charge and $D$ given by

$$D = \frac{E.ep^3}{12.(1-\nu^2)}$$

with $ep$ the thickness of the plate (mm), $\nu$ the Poisson’s coefficient (dimensionless), $E$ the Young’s modulus (DaN/mm$^2$) and $L$ the plate length and width (mm).

To solve the system (23)-(26), we use Gauss-Seidel method (i.e., the relaxation parameter $\omega = 1$). Let’s perform a number of experimental tests to determine the best choice of the penalization parameter $\varepsilon$. For simulation, we retain the same obstacle $q$ as in example 1 and take the same data such that
A Mixed Formulation in Conjunction with the Penalization Method for Solving the Bilaplacian Problem with Obstacle Type Constraints

\( k = 10, \, \varepsilon p = 1, \, \nu = 0.3, \, E = 21000 \) and \( L = 20 \). We choose a tolerance \( tol = 10^{-10} \) and a discretization step \( h = 1/40 \). Now, we display in Table 3, the iteration number (iter) and solutions, for example, at the some nodes: for N1 to N9 (see Figure 2).

Table 3: Solutions at nodes N1 to N9 for different values of \( \varepsilon \)

<table>
<thead>

7. Conclusion

In this work, we have combined the mixed formulation with the classical penalization method for a class of free boundary problems for which the obstacle problem is a representative. The main interest of the mixed formulation is to reduce the 4th order problem to two 2nd order problems. The latter problems require less regularity to the solution and then lead to the solution of two coupled classical laplacian sub-problems with Dirichlet boundary conditions under unilateral constraints. From the numerical point of view, the reduced problems allow to solve coupled systems of small sizes with nice matrices having the $M$-matrix property.

Hence, the computed solutions of the reduced problems require less execution time comparatively to the discrete system associated to the bilaplacian problem. Moreover the coupled problems make use only of $C^0$—continuity ($P1$ Lagrange finite elements) contrary to the bilaplacian problem which requires $C^1$—continuity. However, there is also a possibility to implement a parallel asynchronous algorithm. Through this study, we wanted to test the effectiveness of this technique in order to apply it to other more complex problems than the one presented in this study such as hyperbolic or parabolic type problems arising in hydrodynamics, finance or optimal control with state and/or control constraints.
